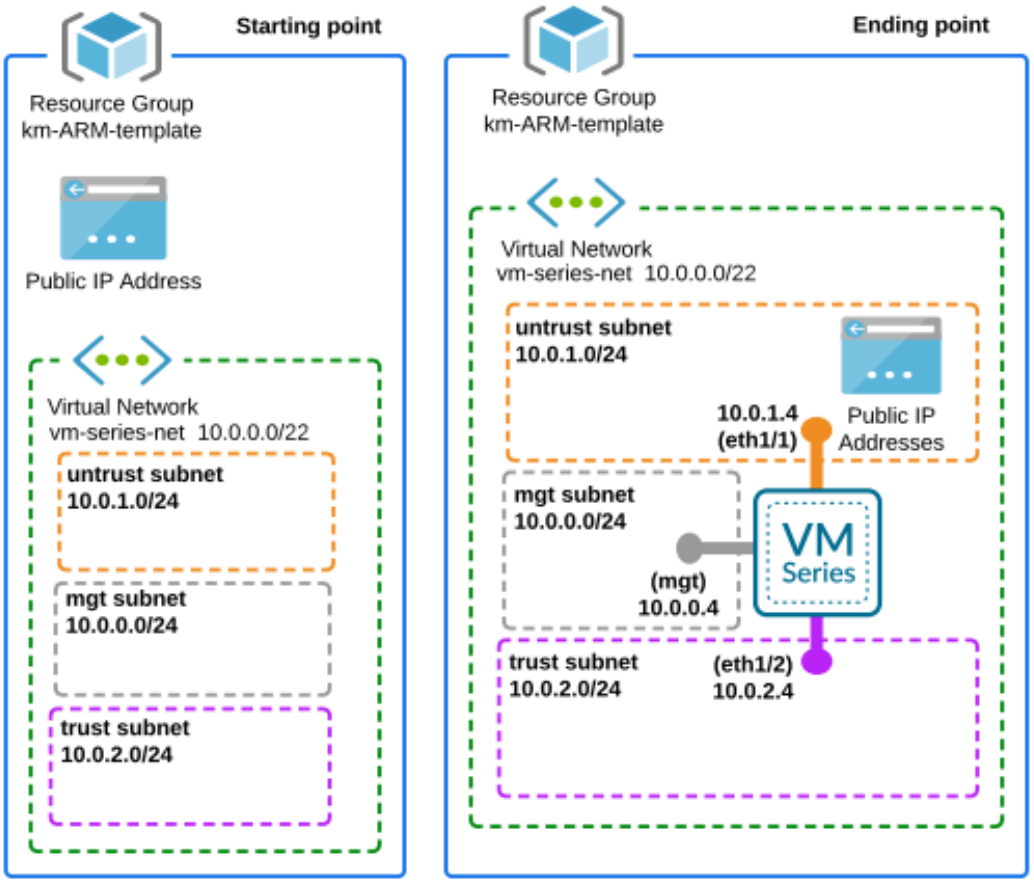
Custom Azure Resource Manager Template for VM-Series NGFW

Template Overview

This document covers a simple template built which deploys the VM-Series into an existing Azure resource group and associates predefined resources to the VM-Series firewall.

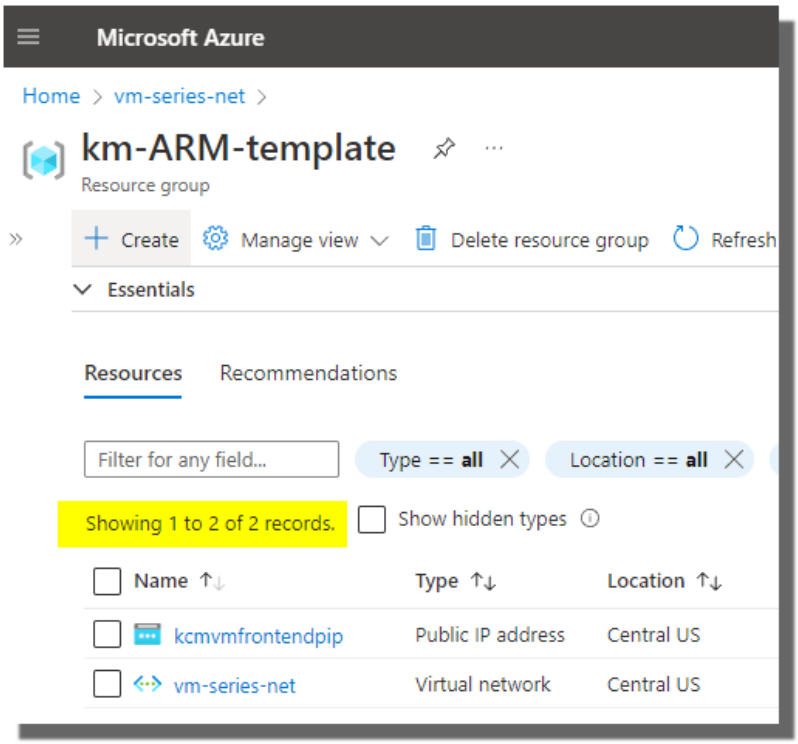
The drawing below illustrates the starting point which is an Azure resource group that includes a virtual network\subnets and public IP address. The ending point displays the result of integrating the VM-Series firewall with the Azure resources using an ARM template.



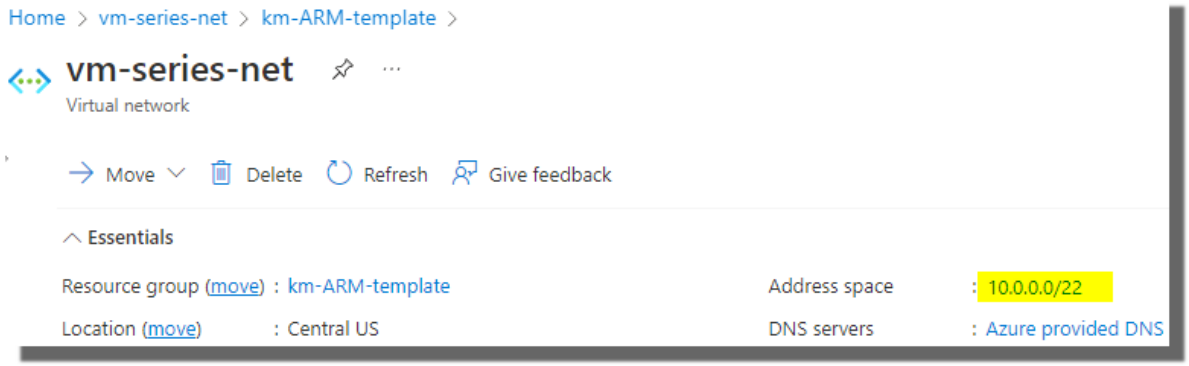
Existing Azure resources

The existing resource group and resources are described in this section.

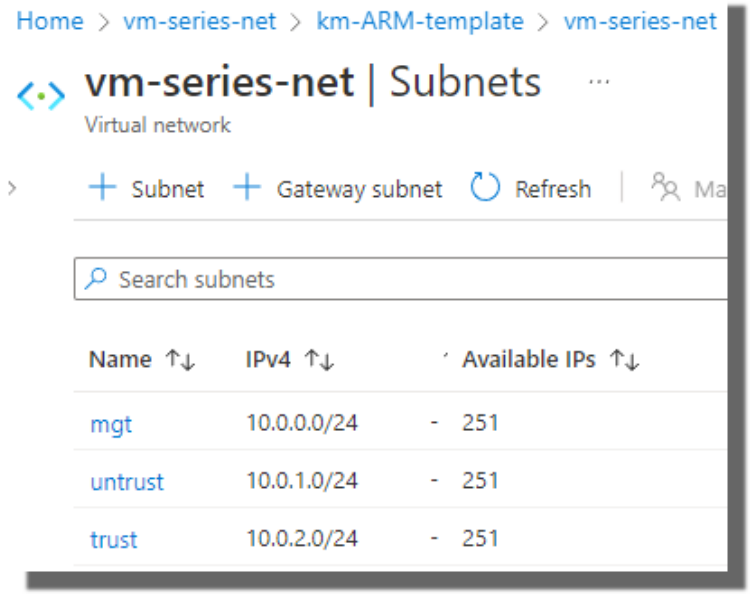
The below example shows a resource group named “km-ARM-template” with two existing resources.
- Vnet named “vm-series-net”
- Public IP address named “kcmvmfrontendpip”



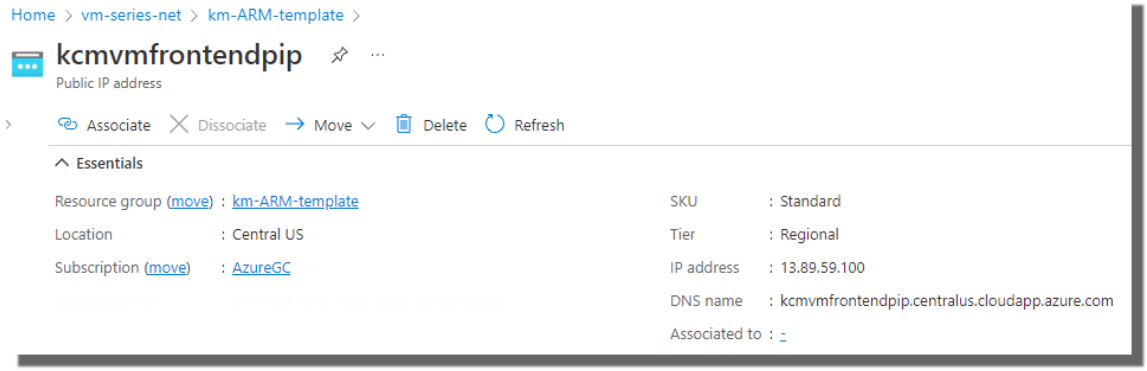
The “vm-series-net” Vnet is comprised of an IP address block 10.0.0.0/22.



The “vm-series-net” Vnet is split up into three subnets named mgt, untrust and trust.



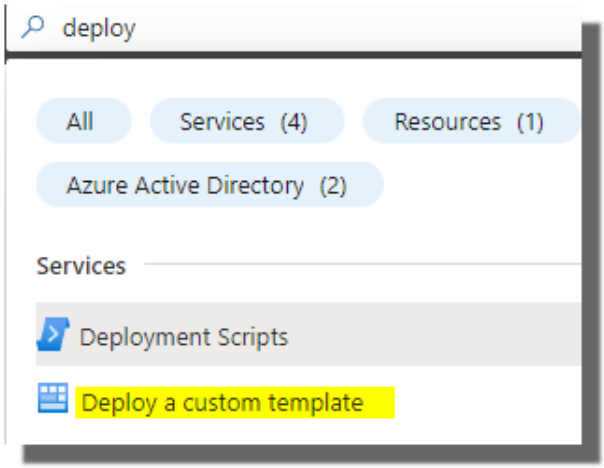
The public IP address “kcmvmfrontendpip” has not been associated to an interface at this time.



Deploy the VM-Series with a custom ARM template

The procedure to launch a VM-Series NGFW into an existing resource group is described in this section.

Step 1. In the Azure portal type "deploy"in the search bar, and select "Deploy a custom template".



Step 2. From the "Custom template" page select "Build your own template in the editor"

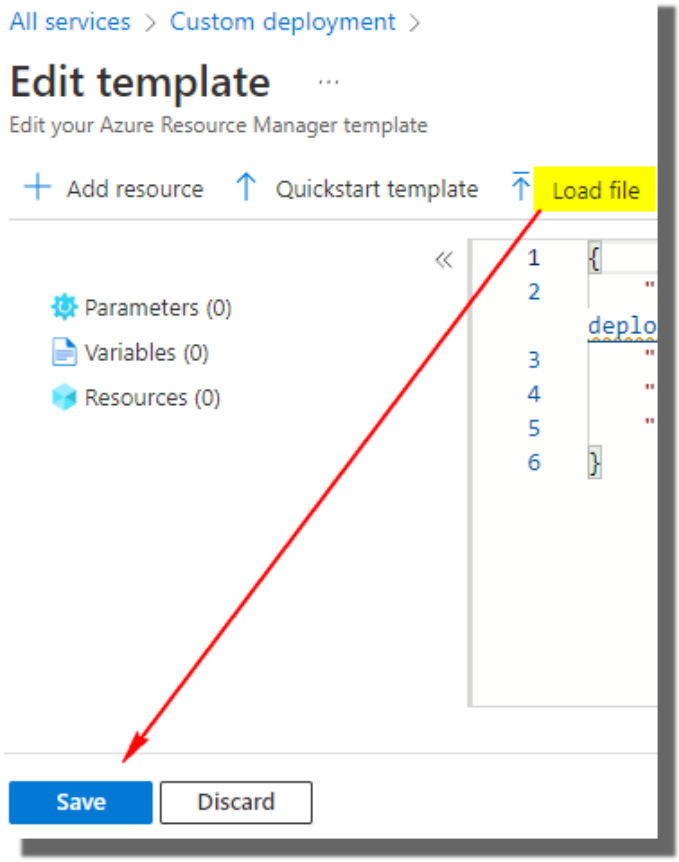
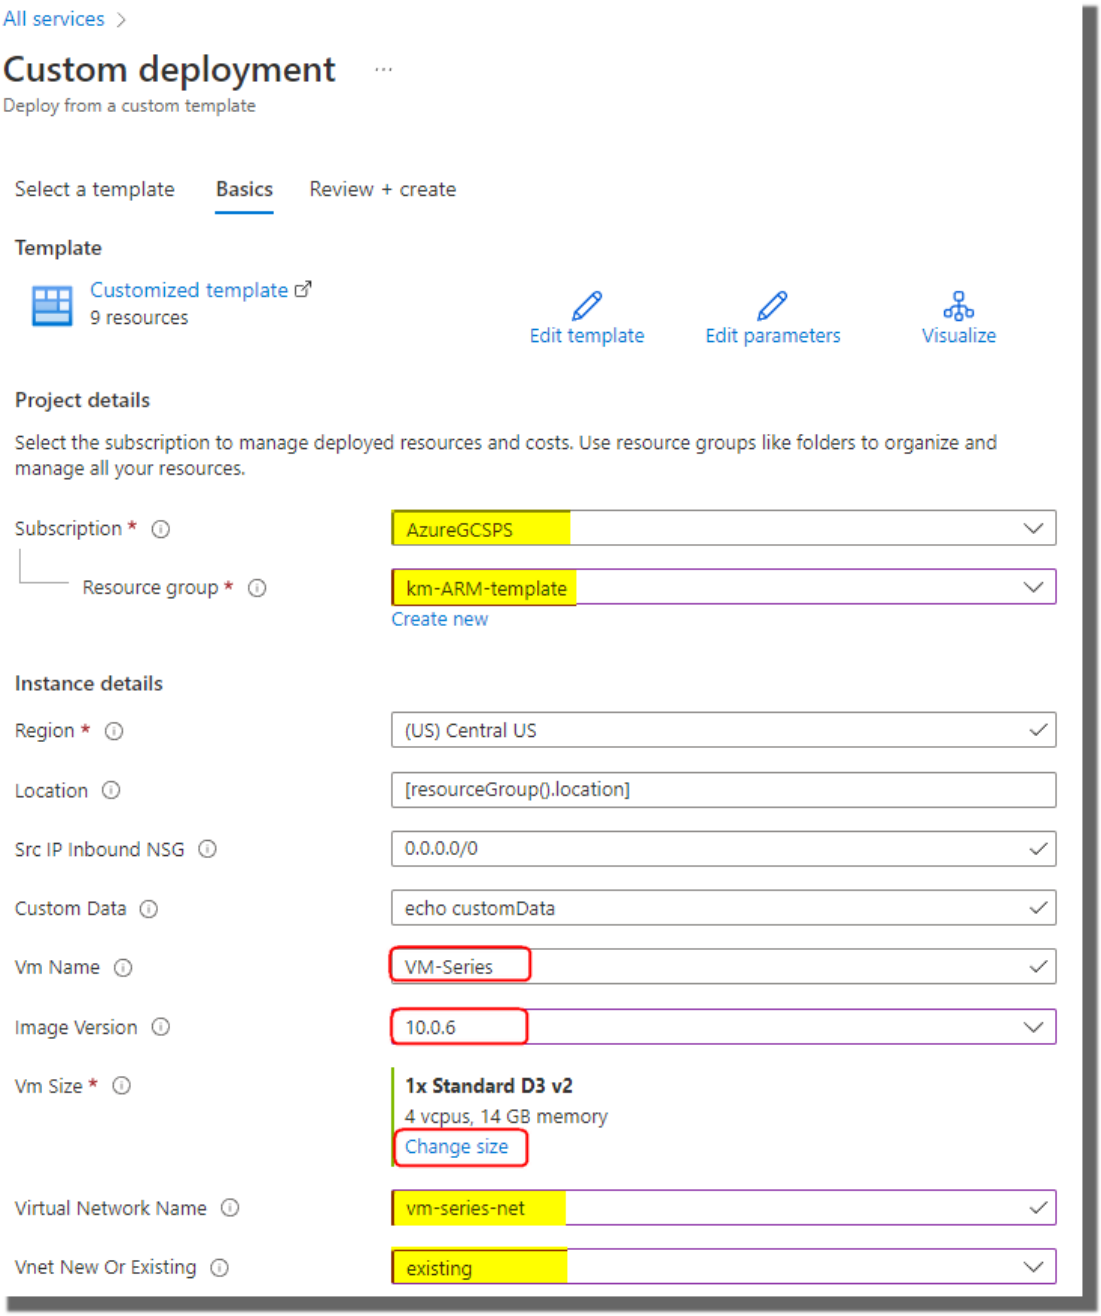
Step 3. Under the "Edit template" screen click "load file" which will allow you to upload the json file (from your desktop or another location) click save to load the file into the template.



Step 4. Under the “Custom deployment” page you will need to fill in information based on your infrastructure. **Highlighted items are mandatory while fields circled in red are optional.**



Step 4b. Continue, all highlighted fields will need to be filled in with data from the existing resource group.

Virtual Network Address Prefixes	10.0.0.0/22
Virtual Network Existing RG Name	km-ARM-template
Subnet0Name	mgt
Subnet1Name	untrust
Subnet2Name	trust
Subnet0Prefix	10.0.0.0/24
Subnet1Prefix	10.0.1.0/24
Subnet2Prefix	10.0.2.0/24
Subnet1Start Address	10.0.1.4
Subnet2Start Address	10.0.2.4
Authentication Type *	(•) Password ( ) SSH Public Key
Admin Password Or Key *	••••••••••••
Admin Username *	paloalto
Public IP New Or Existing	existing
Public IP Address Name *	kcmvmfrontendpip
Public IPRG Name	km-ARM-template
Public IP Allocation Method	Static

You can ignore the last five fields.

- **Bootstrap**
- **Zone**
- **Availability Set Name**
- **Availability Set Platform Fault Domain Count**
- **Availability Set Platform Update Domain Count**

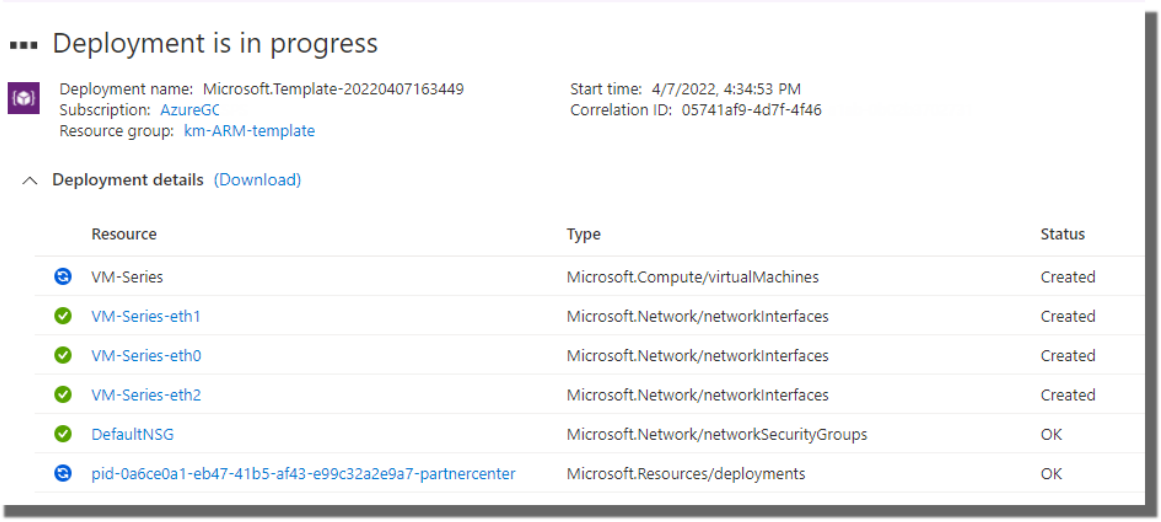
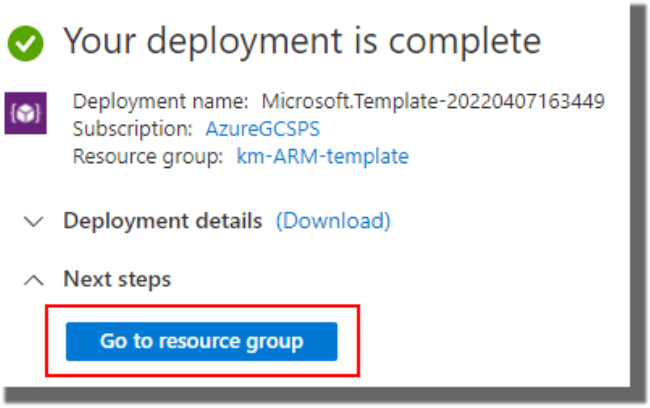
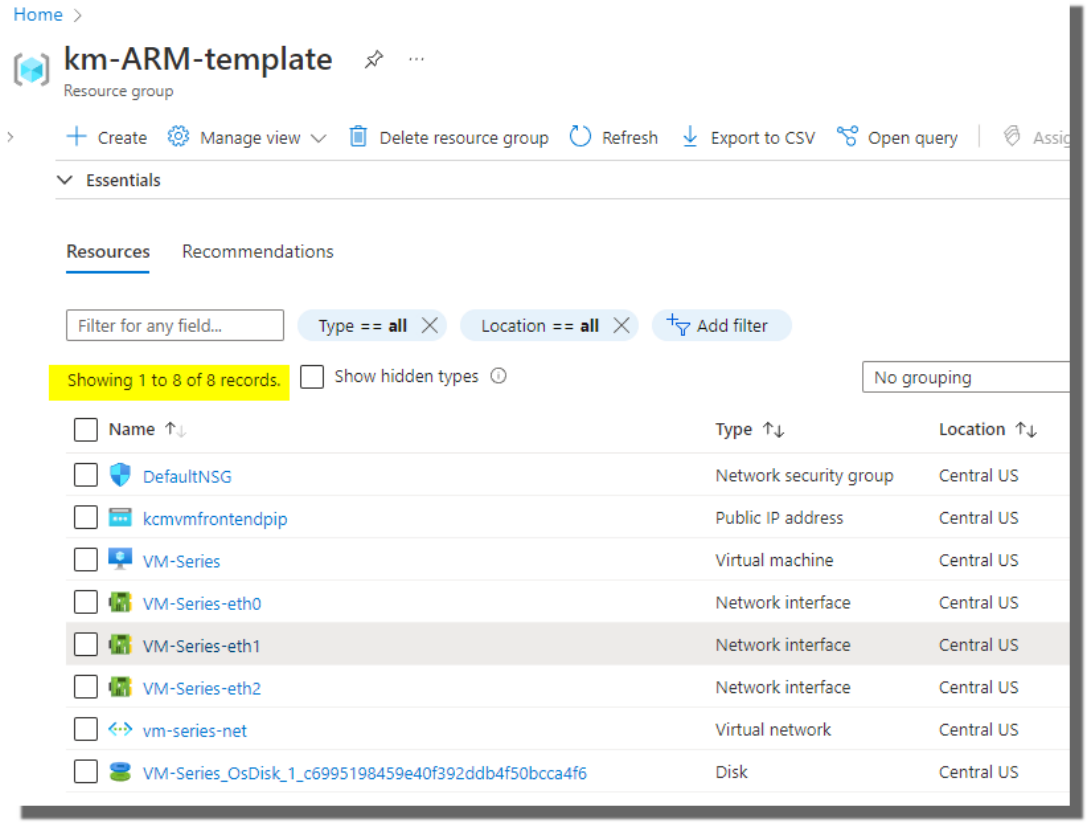
You will now see the notification that the deployment is in progress.



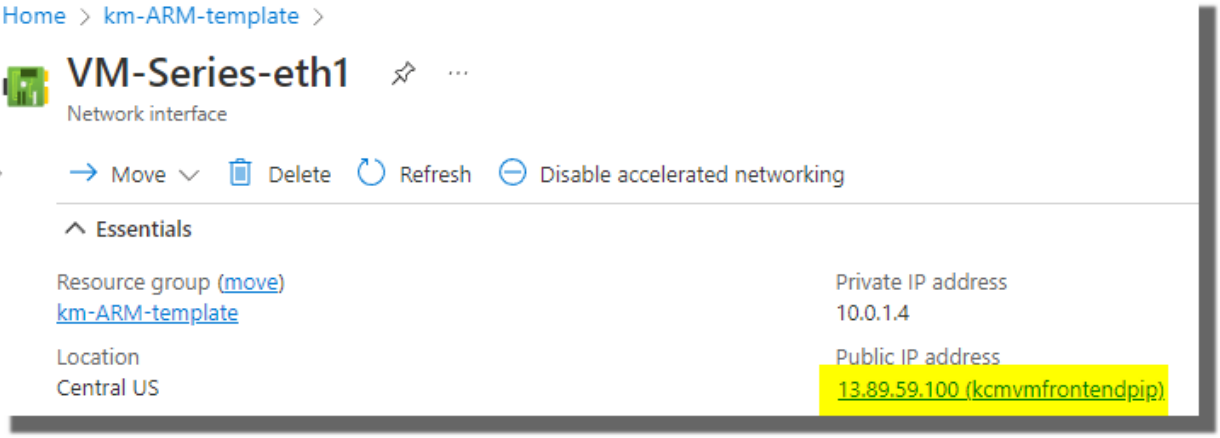
The template overview page will display the deployment status is complete, click “Go to resource group”.



The resource group now included all items built by the template.



Open the configuration for the eth1 interface and see that the existing public IP has been associated to it.



Support Policy This ARM template is released under an as-is, best effort, support policy. The scripts should be seen as community supported and Palo Alto Networks will contribute our expertise as and when possible. We do not provide technical support or help in using or troubleshooting the components of the project through our normal support options such as Palo Alto Networks support teams, or ASC (Authorized Support Centers) partners and backline support options. The underlying product used (the VM-Series firewall) by the scripts or templates are still supported, but the support is only for the product functionality.
